## 1 Problem 1

$a$  in all forms purely changes the shape and direction of the parabola.  $c$  in the expanded form is the y-intercept.  $d$  in the vertex form is the  $x$  coordinate of the vertex.  $h$  in vertex form is the  $y$  coordinate of the vertex.  $x_1$  and  $x_2$  in the factored form represent the two x-intercepts. Increasing  $b$  moves the vertex of the parabola left while maintaining the same shape and y-intercept. Decreasing  $b$  moves the vertex of the parabola right while maintaining the same shape and y-intercept.

## 2 Problem 2

A quadratic does not have a factored form if its  $a$  is positive and its y-intercept is greater than 0 or if its  $a$  is negative and its y-intercept is less than 0.

## 3 Problem 3

$x_1$  and  $x_2$  are solutions to the equation  $0 = ax^2 + bx + c$ , where  $x$  is  $x_1$  and  $x_2$  respectively, the equation  $0 = a(x - d)^2 - h$ , where  $x$  is  $x_1$  and  $x_2$  respectively and the equation  $0 = a(x - x_1)(x - x_2)$ .

## 4 Problem 4

### 4.1 Expanded to Vertex

$a$  is the same in both forms.  $d$  in vertex is  $\frac{b}{2a}$ .  $h$  is  $c - \frac{b^2}{4a^2}$ .

### 4.2 Expanded to Factored

$a$  is the same in both forms.  $x_1$  and  $x_2$  are the two solutions to  $0 = ax^2 + bx + c$ .

### 4.3 Vertex to Expanded

$a$  is the same in both forms. Evaluate  $(x + d)^2$ , then add  $d^2$  to  $c$  and subtract remove the  $d^2$  term.

### 4.4 Vertex to Factored

$a$  is the same in both forms.  $x_1$  and  $x_2$  are the two solutions to  $0 = a(x + d)^2 + h$

### 4.5 Factored to Expanded

$a$  is the same in both forms. Evaluate the  $(x - x_1)(x - x_2)$  to find the expanded form.

### 4.6 Factored to Vertex

Convert to expanded form then to vertex form.

## 5 Problem 4

Let  $(x_0, y_0)$  be a solution to the equation  $y = f(x)$ . If you change the  $x$  to  $x - s$ , increasing  $x_0$  by  $s$  to account for the decrease by  $s$  would also be a solution. Therefore  $x_0 + s, y_0$  is a solution to  $y = f(x - s)$ . If you change  $y$  to  $y - t$ , if you added  $t$  to  $x_0$  it would cancel out the  $t$ , therefore  $(x_0, y_0 + t)$  is a solution. If we combine the two we find that  $(x_0 + s, y_0 + t)$  is always a solution to  $y - t = f(x - s)$  if  $(x_0, y_0)$  is a solution to  $y = f(x)$ . This means that if you increase  $s$ , every point moves right, and if you increase  $t$  every point moves up.
